## Phase-Rule (Two Component System)

### K<sub>2</sub>O - Water System

The K<sub>2</sub>O - Water system is a typical example of a two component system which forms a eutectic mixture. The various features of this system are illustrated in the T-c diagram.

Here Pressure is considered constant at 1-Atmospheric Pressure

Curve AC: - Point A denotes the freezing of water at 1 Atmospheric Pressure. The temperature is 0°C. When increasing quantities of K<sub>2</sub>O is

are added, the freezing point of water is lowered along the curve AC. Thus AC may be called freezing point curve of water.

Along the curve AC, the solution of  $K_2O$  in  $H_2O$  is in contact with  $Ice$ . Thus there are two phases.

Applying the Reduced Phase rule to any point on this curve Area

$$F = C - P + 1 = 2 - 2 + 1$$

$$\therefore F = 1.$$

Thus the system is univariant i.e. has one degree of freedom.

It means that there will be definite composition of the solution corresponding to each temperature.

When further quantities of  $K_2O$  are added, the lowering of freezing point continues along the curve AC till the point C is reached. Here the solution becomes saturated with respect to solid  $K_2O$  and freezes at a constant temperature ( $-22^\circ C$ ) and fixed composition 52%  $K_2O$ .

insol

Curve BC:— This is known as the solubility curve of  $K_2CO_3$  in water at different ~~composition~~ temperature. The solubility increases with rise of temperature and becomes maximum at the point B, i.e. the boiling point of saturated solution. Allow the saturated solution of  $K_2CO_3$  to cool at B.

The solution will freeze along the curve BC, during this, solid  $K_2CO_3$  crystallises. This crystallisation of  $K_2CO_3$  continues till the temperature and composition corresponding to point C is reached. At this point the solution freezes as a whole with fixed composition. Along the curve BC, solid  $K_2CO_3$  is in equilibrium with solution.

Again applying the Reduced Phase rule to this system we obtain

$$F = C - P + 1 = 2 - 2 + 1$$

$$\text{or } F = 1$$

Thus the system is univariant i.e. has one degree of freedom.

(4)

The steep rise of curve BC indicates that the solubility of KJ increases slowly with rise of temperature.

Point C: -

It is the eutectic or cryohydric point. At the point C, the two curves AC and BC meet. This point corresponds to a definite temperature  $-22^{\circ}\text{C}$  and definite composition  $52\% \text{ KJ} + 48\% \text{ JI}$ .

At the point C, JI solution and solid KJ are in equilibrium. This point has no degree of freedom which is evident from phase rule equation.

$$F = C - P + 1 = 2 - 3 + 1$$

$$\text{or } F = 0 \text{ (Zero)}$$

Thus C is a non-variant point.

Area above ACB

If the point lies above the curve AC it means that the dilute solution of KJ is there. But the area above the curve BC represents the concentrated solution of KJ.

Cooling :- Three cases may arise

- (1) Consider a dilute solution represented by the point  $x$ . On cooling, the temperature will lower along the curve  $xy$  without change in composition. This continues till the point  $y$  is reached.

At this point,  $i_c$  separates out. Here the system will become univariant and further cooling will take place along the curve  $yc$ . This is continued till the point  $c$  is reached. At this point  $i_c$  and  $K_9$  freezes as a whole with fixed composition is eutectic mixture.

- (2) Consider a concentrated solution represented by the point  $x'$ . Allow it to cool. This cooling continues without any change in composition along the curve  $x'y'$ . At this point  $y'$ , solid  $K_9$  separates out.

Page No. 6

Further cooling will proceed along the curve  $y'c$  until the point  $c$  is reached. At this point  $i_c$  and  $K_9$  freezes as a whole to give the eutectic mixture  $K_9 = 52\%$  and  $I_c = 48\%$ .

(3) Consider a solution which is represented by the point  $a$ . This point lies vertically above the eutectic point  $c$ . When the solution is allowed to cool, the temperature will lower along the curve  $ac$  until the eutectic point  $c$  is reached. At this point  $i_c$  and  $K_9$  separates out simultaneously. The mixture of  $K_9$  and  $I_c$  deposited at the eutectic point is known as "Cryohydrate".

The End
